Assistant Professor of Medicine
Bernard E. Levine
M.D. Michigan
American Thoracic Society-National Tuberculosis Association Fellow in Pulmonary Disease

From the Departments of Surgery and Medicine, University of Colorado Medical Center, Denver, Colorado, U.S.A.

Summary

The respiratory-distress syndrome in 12 patients was manifested by acute onset of tachypnea, hypoxemia, and loss of compliance after a variety of stimuli; the syndrome did not respond to usual and ordinary methods of respiratory therapy. The clinical and pathological features closely resembled those seen in infants with respiratory distress and to conditions in congestive atelectasis and postperfusion lung. The theoretical relationship of this syndrome to alveolar surface active agent is postulated. Positive end-expiratory pressure was most helpful in combating atelectasis and hypoxemia. Corticosteroids appeared to have value in the treatment of patients with fat-embolism and possibly viral pneumonia.

Methods

All patients were admitted to intensive-care units of the surgical or medical services. Blood-gas studies were performed on arterial blood drawn by percutaneous puncture of either brachial or femoral artery. In most instances, blood was drawn only during a steady state. P_{a}O_{2} measurements were determined with a Clark electrode and oxygen saturation was measured on
How ARDS should be treated in 2017

Protective ventilation in pulmonary and extrapulmonary ARDS - are there any differences?

ARDS - when should I decide for ECMO?
